Abstract. In this paper we study the existence problem for the $p(x)$-Laplacian operator with a nonlinear critical source. We find a local condition on the exponents ensuring the existence of a nontrivial solution that shows that the Pohozaev obstruction does not holds in general in the variable exponent setting. The proof relies on the Concentration–Compactness Principle for variable exponents and the Mountain Pass Theorem.

1. Introduction

In this paper we address the existence problem for the $p(x)$-Laplacian operator with a source that has critical growth in the sense of the Sobolev embeddings. To be precise, we consider the equation

\[
\begin{cases}
-\Delta_{p(x)} u + h|u|^{p(x) - 2} u = |u|^{q(x) - 2} u & \text{in } U, \\
u = 0 & \text{on } \partial U,
\end{cases}
\]

where $U \subset \mathbb{R}^n$ is a smooth bounded domain, $p, q: U \to [1, \infty)$ are log-Hölder continuous functions such that $1 < \inf_U p \leq \sup_U p < n$ and $1 \leq q(x) \leq p^*(x) := np(x)/(n - p(x))$, $x \in U$.

The $p(x)$-Laplacian operator $\Delta_{p(x)}$ is defined, as usual, as

\[
\Delta_{p(x)} u := \text{div}(|\nabla u|^{p(x) - 2} \nabla u).
\]

This operator appears in the study of the so-called electrorheological fluids. We refer to the monograph by Růžička, [25], and its references, for a detailed account. In particular, after some simplifications, the modelling of these fluids lead to solve

\[
\begin{cases}
-\Delta_{p(x)} u = f(\cdot, u, \nabla u) & \text{in } U, \\
u = 0 & \text{on } \partial U,
\end{cases}
\]
for some nonlinear source $f$. In most cases, the source term is taken to be only
dependent on $u$ and so, in order for the usual variational techniques to work, one
needs a control on the growth of $f$ given by the Sobolev embedding.

When the growth of $f$ is subcritical in the sense of the Sobolev embedding the
existence of solution follows easily by applying standard procedures of the calculus
of variations (see e.g. [6, 10, 20, 21, 22] and many others). On the other hand, when
the source term has critical growth, there are only a few results on the existence of
solutions for (1.2) that we will review thoroughly later. Let us just notice for the
moment that these results only provide global existence conditions. This strongly
contrasts with the constant exponent case that has been widely studied since Aubin
and Brezis–Nirenberg’s seminal works [2, 5], and for which it is generally possible to
provide existence conditions that are local in the sense that they involve the behaviour
of the coefficients of the equations (and possibly some relevant geometric quantities)
only in a neighborhood of a point. Our main purpose in this paper is to provide local
existence conditions for the equation (1.1).

In order to study (1.1) by means of variational methods, we introduce the func-
tional $J: W^{1,p(*)}_{0}(U) \to \mathbb{R}$ defined by
\begin{equation}
J(u) := \int_{U} \frac{1}{p(x)} (|\nabla u|^{p(x)} + h(x)|u|^{p(x)}) \, dx - \int_{U} \frac{1}{q(x)} |u|^{q(x)} \, dx.
\end{equation}
This functional is naturally associated to (1.1) in the sense that a weak solution
of (1.1) is a critical point of $J$. We refer to Section 2 for the definition and some
elementary properties of variable exponent spaces.

We need to assume that the smooth function $h$ is such that the functional
\begin{equation}
I(u) := \int_{U} \frac{1}{p(x)} (|\nabla u|^{p(x)} + h(x)|u|^{p(x)}) \, dx
\end{equation}
is coercive in the sense that the norm
$$
\|u\| := \inf \left\{ \lambda > 0 : \int_{U} \frac{\|\nabla u\|^{p(x)} + h(x)|u|^{p(x)}}{\lambda^{p(x)}} \, dx \leq 1 \right\}
$$
is equivalent to the usual norm of $W^{1,p(*)}_{0}(U)$. Notice that a sufficient condition is
$$
\inf_{U} h > -\lambda_{1} \quad \text{where} \quad \lambda_{1} = \inf_{u \in W^{1,p(*)}_{0}(U)} \frac{\int_{U} |\nabla u|^{p(x)} \, dx}{\int_{U} |u|^{p(x)} \, dx} > 0.
$$
In particular $h$ can be negative.

When $\inf_{U} q > \sup_{U} p$, it is easy to show that $J$ satisfies the geometric assump-
tions of the Mountain–Pass Theorem (cf. Section 4). Hence if we assume moreover
that the exponent $q$ is subcritical in the sense that
\begin{equation}
\inf_{U} (p^{*} - q) > 0,
\end{equation}
which implies that the immersion $W^{1,p(*)}_{0}(U) \hookrightarrow L^{q(*)}(U)$ is compact, then $J$ satisfies
the Palais–Smale condition, and the existence of a nontrivial solution to (1.1) follows
easily.

When (1.5) is violated, the immersion $W^{1,p(*)}_{0}(U) \hookrightarrow L^{q(*)}(U)$ does not need to be
compact and so the Palais–Smale condition may fail. The existence of a non-trivial
solution to (1.1) is then a non-trivial problem.
We denote by
\begin{equation}
\mathcal{A} := \{ x \in U : q(x) = p^*(x) \}
\end{equation}
the critical set. We will assume in this work that this critical set is nonempty.

In [23] the authors prove that if \( \mathcal{A} \) is small and there exists a control on the rate of how \( q \) reaches the critical value \( p^* \), then the immersion \( W^{1,p(\cdot)}_0(U) \hookrightarrow L^{q(\cdot)}(U) \) remains compact, and so the usual techniques can be applied. When the immersion fails to be compact they prove that if the subcriticality set \( U \setminus \mathcal{A} \) contains a sufficiently large ball, then (1.1) with \( h = 0 \) has a nonnegative solution.

In [27], using the CCP of [14, 15], a multiplicity problem for (1.1) with \( h = 0 \) and a nonsymmetric subcritical perturbation is analyzed.

More recently, the authors in [12] studied the best Sobolev constant \( S(p(\cdot), q(\cdot), U) \) corresponding to the embedding \( W^{1,p(\cdot)}_0(U) \hookrightarrow L^{q(\cdot)}(U) \), namely
\begin{equation}
S(p(\cdot), q(\cdot), U) = \inf_{u \in W^{1,p(\cdot)}_0(U)} \frac{\| \nabla u \|_{L^{p(\cdot)}(U)}}{\| u \|_{L^{q(\cdot)}(U)}}.
\end{equation}
Using a refinement of the CCP proved in [14], they gave sufficient conditions for the existence of an extremal for \( S(p(\cdot), q(\cdot), U) \), and so the existence of a solution to (1.1) with \( h = 0 \) follows.

We remark that in [12] a bit more than log-Hölder regularity on the exponents \( p \) and \( q \) is required, i.e. it is needed that \( p(\cdot), q(\cdot) : \Omega \to [1, +\infty) \) are continuous functions with modulus of continuity \( \rho(t) \) such that
\begin{equation}
\rho(t) \log(1/t) \to 0 \quad \text{as } t \to 0 + .
\end{equation}
The study of (1.1) posed in the whole \( \mathbb{R}^n \) is analyzed in [1, 16]. In those works the authors studied the problem in the case where \( p, q \) and \( h \) are radial functions and give somewhat restrictive conditions to ensure the existence of a nontrivial radial solution.

From now on we will assume that
\begin{equation}
\sup_U p < \inf_U q.
\end{equation}

Our first result provides a condition for the functional \( J \) defined by (1.3) to satisfy the Palais–Smale condition.

**Theorem 1.1.** Assume that the exponents \( p \) and \( q \) verify (1.8) and, moreover, that the critical set \( \mathcal{A} \) given in (1.6) is nonempty. Then, the functional \( J \) satisfies the Palais–Smale condition at level \( c \in (0, \frac{1}{n} S^n) \) where
\begin{equation}
S := \inf_{x \in \mathcal{A}} \lim_{\epsilon \to 0} S(p(\cdot), q(\cdot), B_\epsilon(x)),
\end{equation}
and \( S(p(\cdot), q(\cdot), B_\epsilon(x)) \) stands for the best Sobolev constant for the domain \( B_\epsilon(x) \) defined in a similar way as in (1.7).
The proof of Theorem 1.1 relies on a precise computation of the constants in the CCP recently proved in [12].

As a corollary, we can apply the Mountain–Pass Theorem to obtain the following necessary existence condition:

**Theorem 1.2.** Under the same assumptions of Theorem 1.1, if there exists $v \in W_0^{1,p(x)}(U)$ such that

$$
\sup_{t>0} J(tv) < \frac{1}{n} S^m,
$$

then (1.1) has a non-trivial nonnegative solution.

Eventually the following result provide a sufficient local condition for (1.11) to hold:

**Theorem 1.3.** Assume that the infimum in the definition (1.10) of $S$ is attained at a point $x_0 \in A$ such that $x_0$ is a local minimum of $p$ and a local maximum of $q$. In particular,

$$
-\Delta p(x_0) \leq 0 \leq -\Delta q(x_0).
$$

Assume, moreover, that $p, q$ are $C^2$ in a neighborhood of $x_0$, and that $h(x_0) < 0$ if $1 < p(x_0) < 2$ ($n \geq 4$), or if $2 \leq p(x_0) < \sqrt{n}$ ($n \geq 5$), that at least one of the two inequalities in (1.12) is strict, but $h(x_0)$ is arbitrary. Under these assumptions (1.11) holds. In particular, (1.1) has a non-trivial nonnegative solution.

In the constant exponent case, the well known Pohozaev obstruction [24] affirms that if $h \geq 0$ and $U$ is starshaped then there are no (positive) solutions to (1.1). Our result shows that for variable $p$ and $q$ and $p(x) \geq 2$ this does not need to be the case, showing a stricking difference between the constant exponent case and the variable exponent one.

2. Preliminaries on variable exponent spaces

In this section we review some preliminary results regarding Lebesgue and Sobolev spaces with variable exponent. All of these results and a comprehensive study of these spaces can be found in [8].

Consider a function $p: U \to [1, +\infty]$ log-Hölder continuous in the sense that

$$
|p(x) - p(y)| \leq \frac{C}{|\log |x - y||}, \quad \text{for } x, y \in U, \ x \neq y
$$

for some constant $C > 0$. This regularity assumptions is not needed to define the Lebesgue and Sobolev spaces with variable $p$ but turns out to be very useful for these Sobolev spaces to enjoy all the usual properties like Sobolev embeddings, Poincaré inequality and so on. We will therefore assume it from now for simplicity.

The variable exponent Lebesgue space $L^{p(x)}(U)$ is defined by

$$
L^{p(x)}(U) = \left\{ u \in L^1_{\text{loc}}(U) : \int_U |u(x)|^{p(x)} \, dx < \infty \right\}.
$$

This space is endowed with the norm

$$
\|u\|_{L^{p(x)}(U)} = \inf \left\{ \lambda > 0 : \int_U \frac{u(x)}{\lambda}^{p(x)} \, dx \leq 1 \right\}.
$$
The variable exponent Sobolev space $W^{1,p(x)}(U)$ is defined by

$$W^{1,p(x)}(U) = \{ u \in W^{1,1}_{\text{loc}}(U) : u \in L^{p(x)}(U) \text{ and } |\nabla u| \in L^{p(x)}(U) \}.$$ 

The corresponding norm for this space is

$$\|u\|_{W^{1,p(x)}(U)} = \|u\|_{L^{p(x)}(U)} + \|\nabla u\|_{L^{p(x)}(U)}.$$ 

Define $W^{1,p(x)}_0(U)$ as the closure of $C_0^\infty(U)$ with respect to the $W^{1,p(x)}(U)$ norm. The spaces $L^{p(x)}(U)$, $W^{1,p(x)}(U)$ and $W^{1,p(x)}_0(U)$ are separable and reflexive Banach spaces when $1 < p^- \leq p^+ < \infty$, where $p^- := \text{ess inf}_U p$ and $p^+ := \text{ess sup}_U p$.

As usual, we denote the conjugate exponent of $p(x)$ by $p'(x) = p(x)/(p(x) - 1)$ and the Sobolev exponent by

$$p^*(x) = \begin{cases} \frac{Np(x)}{N-p(x)} & \text{if } p(x) < N, \\ \infty & \text{if } p(x) \geq N. \end{cases}$$

The following result is proved in [18] (see also [11] and [8], pp. 79, Lemma 3.2.20 (3.2.23)).

**Proposition 2.1.** (Hölder-type inequality) Let $f \in L^{p(x)}(U)$ and $g \in L^{q(x)}(U)$. Then the following inequality holds

$$\|fg\|_{L^{p(x)}(U)} \leq \left( \left( \frac{S}{p} \right)^+ + \left( \frac{S}{q} \right)^+ \right) \|f\|_{L^{p(x)}(U)} \|g\|_{L^{q(x)}(U)},$$

where

$$\frac{1}{s(x)} = \frac{1}{p(x)} + \frac{1}{q(x)}.$$

The Sobolev embedding Theorem is also proved in [11], Theorem 2.3.

**Proposition 2.2.** (Sobolev embedding) Let $q : U \in [1, +\infty)$ be a measurable function such that $1 \leq q(x) \leq p^*(x) < \infty$ for all $x \in \overline{U}$. Then there is a continuous embedding

$$W^{1,p(x)}(U) \hookrightarrow L^{q(x)}(U).$$

Moreover, if $\inf_U (p^* - q) > 0$ then, the embedding is compact.

As in the constant exponent spaces, Poincaré inequality holds true (see [8], pp. 249, Theorem 8.2.4).

**Proposition 2.3.** (Poincaré inequality) There is a constant $C > 0$, $C = C(U)$, such that

$$\|u\|_{L^{q(x)}(U)} \leq C \|\nabla u\|_{L^{p(x)}(U)},$$

for all $u \in W^{1,p(x)}_0(U)$.

It follows from the Poincaré inequality that $\|\nabla u\|_{L^{p(x)}(U)}$ and $\|u\|_{W^{1,p(x)}(U)}$ are equivalent norms on $W^{1,p(x)}_0(U)$, in particular.

Throughout this paper the following notation will be used: Given $q : U \rightarrow \mathbb{R}$ bounded, we denote

$$q^+ := \sup_U q(x), \quad q^- := \inf_U q(x).$$

The following proposition is also proved in [11] and it will be most useful (see also [8], Chapter 2, Section 1).
Proposition 2.4. Set \( \rho(u) := \int_U |u(x)|^{p(x)} \, dx \). For \( u \in L^{p(\cdot)}(U) \) and \( \{u_k\}_{k \in \mathbb{N}} \subset L^{p(\cdot)}(U) \), we have

\[
\begin{align*}
\text{(2.1)} \quad u \neq 0 & \Rightarrow \left( \|u\|_{L^{p(\cdot)}(U)} = \lambda \left\Rightarrow \rho\left(\frac{u}{\lambda}\right) = 1\right) , \\
\text{(2.2)} \quad \|u\|_{L^{p(\cdot)}(U)} < 1 (=1; >1) & \iff \rho(u) < 1 (=1; >1) , \\
\text{(2.3)} \quad \|u\|_{L^{p(\cdot)}(U)} > 1 & \Rightarrow \|u\|_{L^{p(\cdot)}(U)}^{p^{-}} \leq \rho(u) \leq \|u\|_{L^{p(\cdot)}(U)}^{p^{+}} , \\
\text{(2.4)} \quad \|u\|_{L^{p(\cdot)}(U)} < 1 & \Rightarrow \|u\|_{L^{p(\cdot)}(U)}^{p^{+}} \leq \rho(u) \leq \|u\|_{L^{p(\cdot)}(U)}^{p^{-}} , \\
\text{(2.5)} \quad \lim_{k \to \infty} \|u_k\|_{L^{p(\cdot)}(U)} = 0 & \iff \lim_{k \to \infty} \rho(u_k) = 0 , \\
\text{(2.6)} \quad \lim_{k \to \infty} \|u_k\|_{L^{p(\cdot)}(U)} = \infty & \iff \lim_{k \to \infty} \rho(u_k) = \infty .
\end{align*}
\]

The following Lemma is the extension to variable exponents of the well-known Brezis–Lieb Lemma (see [4]). The proof is analogous to that of [4]. See Lemma 3.4 in [14].

Lemma 2.5. Let \( f_n \to f \) a.e. and \( f_n \to f \) in \( L^{p(\cdot)}(U) \) then

\[
\lim_{n \to \infty} \left( \int_U |f_n|^{p(x)} \, dx - \int_U |f - f_n|^{p(x)} \, dx \right) = \int_U |f|^{p(x)} \, dx .
\]

For much more on these spaces, we refer to [8].

3. Proof of Theorem 1.1

In this section we verify that the functional \( J \) defined by (1.3) satisfies the Palais–Smale condition (PS for short) for energy levels below the critical one \( \frac{1}{n} S^n \).

Recall that \( J \) is said to satisfy the PS condition if any PS sequence for \( J \) has a strongly converging subsequence, where a sequence \( \{u_k\}_{k \in \mathbb{N}} \subset W_{0}^{1,p(\cdot)}(U) \) is called a PS-sequence for \( J \) if

i. The sequence \( \{J(u_k)\}_{k \in \mathbb{N}} \) is bounded, and

ii. \( DJ(u_k) \to 0 \) strongly in the dual space \( \left(W_{0}^{1,p(\cdot)}(U)\right)' \).

The scheme of the proof is classical (see e.g. [26]) but relies on a version of Lions’ concentration–compactness principle adapted to the variable exponent setting in [14] and then refined in [12].

Let \( \{u_k\}_{k \in \mathbb{N}} \subset W_{0}^{1,p(\cdot)}(U) \) be a PS-sequence for \( J \). Recalling that the functional \( I \) defined by (1.4) is assumed to be coercive, it then follows that \( \{u_k\}_{k \in \mathbb{N}} \) is bounded in \( W_{0}^{1,p(\cdot)}(U) \). In fact, for \( \kappa \) large, we have that

\[
c + 1 \geq J(u_k) - \frac{1}{q} \langle DJ(u_k), u_k \rangle \geq \left(\frac{1}{p^{+}} - \frac{1}{q} \right) \int_U |\nabla u_k|^{p(x)} + h(x)|u_k|^{p(x)} \, dx - \int_U \left(\frac{1}{q(x)} - \frac{1}{q} \right) |u_k|^{q(x)} \, dx \geq \left(\frac{1}{p^{+}} - \frac{1}{q} \right) \int_U |\nabla u_k|^{p(x)} + h(x)|u_k|^{p(x)} \, dx .
\]

from where the claim follows recalling assumption (1.9).

We may thus assume that \( u_k \rightharpoonup u \) weakly in \( W_{0}^{1,p(\cdot)}(U) \). We claim that \( u \) turns out to be a weak solution to (1.1). In fact, since \( u_k \rightharpoonup u \) weakly in \( W_{0}^{1,p(\cdot)}(U) \) it
follows that
\[
|\nabla u_k|^{p(-2)}\nabla u_k \rightharpoonup |\nabla u|^{p(-2)}\nabla u \quad \text{weakly in } L^{p'}(U),
\]
\[
|u_k|^{p(-2)}u_k \rightharpoonup |u|^{p(-2)}u \quad \text{weakly in } L^{p'}(U),
\]
\[
|u_k|^{q(-2)}u_k \rightharpoonup |u|^{q(-2)}u \quad \text{weakly in } L^{p'}(U).
\]
So
\[
0 = \lim_{k \to \infty} \langle DJ(u_k), \phi \rangle
\]
\[
(3.1)
\]
\[
= \lim_{k \to \infty} \int_U |\nabla u_k|^{p(x)-2}\nabla u_k \nabla \phi + h|u_k|^{p(x)-2}u_k \phi \, dx - \int_U |u_k|^{q(x)-2}u_k \phi
\]
\[
= \int_U |\nabla u|^{p(x)-2}\nabla u \nabla \phi + h|u|^{p(x)-2}u \phi \, dx - \int_U |u|^{q(x)-2}u \phi,
\]
for every \( \phi \in C^\infty_0(U) \). This proves that \( u \) is a weak solution of (1.1).

By the CCP for variable exponents (see [14] and the refinement proved in [12]) it holds that
\[
|u_k|^{q(\cdot)} \to \nu = |u|^{q(\cdot)} + \sum_{i \in I} \nu_i \delta_{x_i} \quad \text{weakly in the sense of measures},
\]
\[
|\nabla u_k|^{p(\cdot)} \to \mu \geq |\nabla u|^{p(\cdot)} + \sum_{i \in I} \mu_i \delta_{x_i} \quad \text{weakly in the sense of measures},
\]
\[
S\nu_i^{1/p'(x_i)} \leq \mu_i^{1/p'(x_i)},
\]
where \( I \) is a finite set, \( \{\nu_i\}_{i \in I} \) and \( \{\mu_i\}_{i \in I} \) are positive numbers and the points \( \{x_i\}_{i \in I} \) belong to the critical set \( A \) defined in (1.6).

It is not difficult to check (arguing as in (3.1)) that \( v_k := u_k - u \) is PS-sequence for \( \tilde{J}(v) := J(v) - \int_U \frac{1}{p(x)} h|v|^{p(x)} \). Now, by Lemma 2.5 we get
\[
J(u_k) - J(u) = \int_U \frac{1}{p(x)} \left[|\nabla v_k|^{p(x)} + h|v_k|^{p(x)}\right] \, dx - \int_U \frac{1}{q(x)} |v_k|^{q(x)} \, dx + o(1)
\]
\[
= \tilde{J}(v_k) + \int_U \frac{1}{p(x)} h|v_k|^{p(x)} \, dx + o(1) = \tilde{J}(v_k) + o(1).
\]
Since \( u \) is a weak solution of (1.1), and since \( p^+ < q^- \),
\[
J(u) \geq \frac{1}{p^+} \int_U \left(|\nabla u|^{p(x)} + h(x)|u|^{p(x)}\right) \, dx - \frac{1}{q^-} \int_U |u|^{q(x)} \, dx
\]
\[
= \left(\frac{1}{p^+} - \frac{1}{q^-}\right) \int_U |u|^{q(x)} \, dx \geq 0.
\]
Therefore,
\[
J(u_k) \geq \tilde{J}(v_k) + o(1).
\]
Let \( \phi \in C^\infty_0(U) \). As \( D\tilde{J}(v_k) \to 0 \), we have
\[
o(1) = \langle D\tilde{J}(v_k), v_k \phi \rangle
\]
\[
= \int_U |\nabla v_k|^{p(x)} \phi \, dx - \int_U |v_k|^{q(x)} \phi \, dx + \int_U |\nabla v_k|^{p(x)-2}\nabla v_k \nabla \phi v_k \, dx
\]
\[
= A - B + C.
\]
Since \( v_k \to 0 \) weakly in \( W_0^{1,p_r}(U) \) it is easy to see that \( C \to 0 \) as \( k \to \infty \). By means of Lemma 2.5 it follows that
\[
A \to \int_U \phi \, d\tilde{\mu} \quad \text{and} \quad B \to \int_U \phi \, d\tilde{\nu},
\]
where \( \tilde{\mu} = \mu - |\nabla u|^{p(x)} \) and \( \tilde{\nu} = \nu - |u|^{q(x)} \). So we conclude that \( \tilde{\mu} = \tilde{\nu} \). In particular, \( \nu_i \geq \mu_i \) (\( i \in I \)) from where we obtain that \( \nu_i \geq S^n \). Hence
\[
c = \lim_{k \to \infty} J(u_k) \geq \lim_{k \to \infty} \tilde{J}(v_k) = \int \left( \frac{1}{p(x)} \, d\tilde{\mu} - \int \frac{1}{q(x)} \, d\tilde{\nu} \right)
\]
which tends to \( -\infty \) as \( \nu_i \to \infty \) big enough. Indeed, for \( \nu_i \geq 0 \),
\[
\left( \frac{1}{p(x)} - \frac{1}{q(x)} \right) \, d\nu = \sum_{i \in I} \left( \frac{1}{p(x_i)} - \frac{1}{p^*(x_i)} \right) \nu_i \geq \#(I) \frac{1}{n} S^n.
\]
We deduce that if \( c < \frac{1}{n} S^n \) then \( I \) must be empty implying that \( u_k \to u \) strongly in \( W_0^{1,p_r}(U) \).

\[
\square
\]

4. Proof of Theorem 1.2

The proof of Theorem 1.2 is an immediate consequence of the Mountain Pass Theorem, Theorem 1.1 and assumption (1.11).

In fact, it suffices to verify that \( J \) has the Mountain Pass geometry in the sense that

1. \( J(0) = 0 \) (this is obvious),
2. there exist \( r, \rho > 0 \) such that \( J(v) \geq \rho \) if \( \|v\|_{W_0^{1,p_r}(U)} = r \), and
3. there exist some \( v, \|v\|_{W_0^{1,p_r}(U)} > r \), such that \( J(v) \leq 0 \).

Concerning the latter condition notice that, given some \( u \not\equiv 0 \), we have that \( \tilde{J}(tu) < 0 \) for \( t > 0 \) big enough. Indeed, for \( t > 1 \),
\[
\tilde{J}(tu) = \int U \frac{t^{p(x)}}{p(x)} (|\nabla u|^{p(x)} + h(x)|u|^{p(x)}) \, dx - \int U \frac{t^{q(x)}}{q(x)} |u|^{q(x)} \, dx
\]
which tends to \( -\infty \) as \( t \to +\infty \) since \( q^- > p^+ \).

It remains to verify condition (2). If \( \|v\|_{W_0^{1,p_r}(U)} = r \) small enough, then
\[
\int_U |\nabla u|^{p(x)} + h|u|^{p(x)} \, dx \geq c\|v\|_{W_0^{1,p_r}(U)}^{p^+}
\]
and
\[
\|v\|_{L^{q^-(U)}} \leq C\|v\|_{W_0^{1,p_r}(U)} = Cr < 1,
\]
so
\[
\int_U |v|^{q(x)} \, dx \leq C\|v\|_{W_0^{1,p_r}(U)}^{q^-}.
\]
Therefore
\[
J(v) \geq \frac{c}{p^+} r^{p^+} - \frac{C}{q^-} r^{q^-} > 0,
\]
since \( p^+ < q^- \). This completes the proof.

\[
\square
\]
5. Proof of Theorem 1.3

Let \( x_0 \in A \) be such that
\[
S := \inf_{x \in A} \lim_{\epsilon \to 0} S(p(\cdot), q(\cdot), B_\epsilon(x)) = \lim_{\epsilon \to 0} S(p(\cdot), q(\cdot), B_\epsilon(x_0)).
\]

For ease of notation we assume that \( x_0 = 0 \), write \( p = p(0) \) and observe that \( q = q(0) = p^* \). From Theorem 6.1 in [12], we have that if \( 0 \) is a local maximum of \( q \) and a local minimum of \( p \), then
\[
S = \lim_{\epsilon \to 0} S(p(\cdot), q(\cdot), B_\epsilon(0)) = K(n, p)^{-1},
\]
where \( K(n, p) \) is the best constant in the Sobolev inequality in \( \mathbb{R}^n \), i.e.,
\[
K(n, p)^{-1} = \inf_{v \in W^{1,p} (\mathbb{R}^n)} \frac{\| \nabla v \|_{L^p(\mathbb{R}^n)}}{\| v \|_{L^{p^*}(\mathbb{R}^n)}}.
\]

Let \( U \) be an extremal for the constant \( K(n, p) \). That is, \( U \) verifies
\[
K(n, p)^{-1} = \frac{\| \nabla U \|_{L^p(\mathbb{R}^n)}}{\| U \|_{L^{p^*}(\mathbb{R}^n)}}.
\]

It is well known, see [2, 28], that \( U \) can be given by the formula
\[
U(x) = \left(1 + |x|^{\frac{2}{p-1}} \right)^{-\frac{n+p}{p}}.
\]

Moreover, any extremal for \( K(n, p) \) is obtained by a translation and a dilation of \( U \) in the form
\[
U_{\epsilon, x_0}(x) = \epsilon^{-\frac{n+p}{p}} U((x - x_0)/\epsilon).
\]

Given \( \delta > 0 \) small we take a cut-off function \( \eta \in C^\infty_c(B_{2\delta}, [0, 1]) \) such that \( \eta \equiv 1 \) in \( B_\delta \). We then consider the test-function
\[
u_\epsilon(x) = U_{\epsilon, 0}(x) \eta(x).
\]

For this test function we have:

**Proposition 5.1.** Assume that \( 0 \) is a critical point of \( p \) and \( q \). We have

- If \( p \leq \frac{n}{2} \),

\[
\int_{\mathbb{R}^n} f(x) u_\epsilon^q(x) \, dx = A_0 + A_1 \epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon)
\]

with
\[
A_0 = f(0) \int_{\mathbb{R}^n} U^{p^*} \, dx, \quad A_1 = -\frac{n-p}{p} f(0) \frac{1}{2} \int_{\mathbb{R}^n} U^{p^*}(D^2 q(0) x, x) \, dx.
\]

- If \( p < \min\{\sqrt{n}, \frac{n+2}{3}\} \),

\[
\int_{\mathbb{R}^n} f(x) |\nabla u_\epsilon|^{p(x)} \, dx = B_0 + B_1 \epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon)
\]

with
\[
B_0 = f(0) \int_{\mathbb{R}^n} |\nabla U|^p \, dx, \quad B_1 = -\frac{n-f(0)}{p} \frac{1}{2} \int_{\mathbb{R}^n} |\nabla U|^p(D^2 p(0) x, x) \, dx.
\]
If \( p < \sqrt{n}, \)

\[
\int_{\mathbb{R}^n} f(x)\left|u_\epsilon^{p(x)}\right|^p \, dx = C_0 \epsilon^p + o(\epsilon^p) \quad \text{with} \quad C_0 = f(0) \int_{\mathbb{R}^n} U^p \, dx.
\]

**Remark 5.2.** Observe that if \( g(x) \) is a radial function, then

\[
\int_{\mathbb{R}^n} g(x)(Ax, x) \, dx = \text{tr}(A) \int_{\mathbb{R}^n} g(x)x_i^2 \, dx = \frac{\text{tr}(A)}{n} \int_{\mathbb{R}^n} g(x)|x|^2 \, dx,
\]

for any \( A \in \mathbb{R}^{n \times n} \) (with adequate decaying assumptions at infinity on \( g \)). In fact, this is a consequence of the fact that, for \( i \neq j, \)

\[
\int_{\mathbb{R}^n} g(x)x_i x_j \, dx = 0.
\]

With this observation, we easily conclude that

\[
A_1 = -\frac{f(0)}{p^*} \Delta q(0) \int_{\mathbb{R}^n} U^{p^*}|x|^2 \, dx
\]

and

\[
B_1 = -\frac{f(0)}{2p} \Delta p(0) \int_{\mathbb{R}^n} |\nabla U|^p |x|^2 \, dx.
\]

We postpone the proof of this proposition to Section 6.

As \( U \) is an extremal for \( K(n, p) \) it follows that \( U \) verifies

\[
-\Delta_p U = \frac{K(n, p)^{-p}}{\|U\|_{L^{p^*}(\mathbb{R}^n)}} U^{p^*-1} = CU^{p^*-1}.
\]

Then \( V = C^{\frac{1}{p^*-p}} U = \frac{K(n, p)^{-\frac{n-p}{p^*-p}}}{\|U\|_{L^{p^*}(\mathbb{R}^n)}} U \) solves \(-\Delta_p V = V^{p^*-1}\) and satisfy

\[
\|\nabla V\|_{L^p(\mathbb{R}^n)} = K(n, p)^{-n/p}.
\]

Consider the test function

\[
v_\epsilon(x) = \epsilon^{-\frac{n}{n-p}} V(x/\epsilon), \quad \eta(x) = C_{\frac{1}{p^*-p}} u_\epsilon(x).
\]

Using the previous proposition we immediately obtain

**Proposition 5.3.** Assume that 0 is a critical point of \( p \) and \( q \). If \( p < \min\{\sqrt{n}, \frac{n+2}{3}\} \), then

\[
\int_{\mathbb{R}^n} f(x)v_\epsilon^{q(x)} \, dx = f(0) K(n, p)^{-n} + f(0) A \epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon),
\]

\[
\int_{\mathbb{R}^n} f(x)|\nabla v_\epsilon|^{p(x)} \, dx = f(0) K(n, p)^{-n} + f(0) B \epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon),
\]

\[
\int_{\mathbb{R}^n} f(x)|v_\epsilon|^{p(x)} \, dx = f(0) C \epsilon^p + o(\epsilon^p),
\]

with

\[
A = -\frac{\Delta q(0)}{2p^*} K(n, p)^{-n} \|U\|_{L^{p^*}} \int_{\mathbb{R}^n} |x|^2 U^{p^*} \, dx,
\]

\[
B = -\frac{\Delta p(0)}{2p} K(n, p)^{p-n} \|U\|_{L^{p^*}} \int_{\mathbb{R}^n} |x|^2 |\nabla U|^p \, dx,
\]

\[
C = K(n, p)^{p-n} \|U\|_{L^{p^*}} \int_{\mathbb{R}^n} U^p \, dx.
\]
Using \( v_\epsilon \) as a test-function in (1.11) we can see that there exists \( t_0 > 1 \) such that \( J(tv_\epsilon) < 0 \) for \( t > t_0 \). Now if \( p < 2 \), we can write
\[
f_\epsilon(t) := J(tv_\epsilon) = f_0(t) + \epsilon^p f_1(t) + o(\epsilon^p)
\]
\( C^1 \)-uniformly in \( t \in [0, t_0] \), with
\[
f_0(t) = K(n, p)^{-n} \left( \frac{\epsilon^p}{p} - \frac{\epsilon^{p^*}}{p^*} \right) \quad \text{and} \quad f_1(t) = \frac{1}{p} \epsilon^p h(0) C.
\]
Notice that \( f_0 \) reaches its maximum in \( [0, t_0] \) at \( t = 1 \). Moreover, it is a nondegenerate maximum since \( f_0''(1) = (p - p^*)K^{-n} \neq 0 \). It follows that \( f_\epsilon \) reaches a maximum at \( t_\epsilon = 1 + a\epsilon^p + o(\epsilon^p) \) for \( a = -\frac{f_0''(1)}{f_0'(1)} \). Hence
\[
\sup_{t > 0} J(tv_\epsilon) = J(t_\epsilon v_\epsilon) = \frac{1}{n} K(n, p)^{-n} + f_1(1) \epsilon^p + o(\epsilon^p)
\]
Then if \( h(0) < 0 \) we get \( \sup_{t > 0} J(tv_\epsilon) < \frac{1}{n} K(n, p)^{-n} \).

We now assume that \( p \geq 2 \). Then
\[
f_\epsilon(t) = J(tv_\epsilon) = f_0(t) + \tilde{f}_1(t) \epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon),
\]
\( C^1 \)-uniformly in \( t \in [0, t_0] \), with
\[
\tilde{f}_1(t) = \frac{\epsilon^{p^*}}{p^*} A - \frac{\epsilon^p}{p} B.
\]
As before \( f_\epsilon \) reaches its maximum at \( t_\epsilon = 1 + a\epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon) \) with \( a = -\frac{f_0''(1)}{f_0'(1)} \). Hence
\[
\sup_{t > 0} J(tv_\epsilon) = J(t_\epsilon v_\epsilon) = f_0(1) + \tilde{f}_1(1) \epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon)
\]
\[
= \frac{1}{n} K(n, p)^{-n} + \tilde{f}_1(1) \epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon).
\]
We thus need \( \tilde{f}_1(1) < 0 \), i.e.,
\[
\Delta p(0) < -\Delta q(0) (p/p^*)^2 D(n, p), \tag{5.5}
\]
where
\[
D(n, p) := \int_{\mathbb{R}^n} \frac{|\nabla U|^p}{U^p} \, dx \int_{\mathbb{R}^n} |x|^2 U^{p^*} \, dx \int_{\mathbb{R}^n} U^{p^*} \, dx \int_{\mathbb{R}^n} |x|^2 |\nabla U|^p \, dx.
\]
Since 0 is a local maximum of \( q \) and a local minimum of \( p \) we already know that (1.12) holds. Then if one of the two inequalities in (1.12) is strict we see that (5.5) holds.

This ends the proof of Theorem 1.3. \( \square \)

As a final remark, we notice that we can compute \( D(n, p) \) exactly. To do this let
\[
I_p^q := \int_0^\infty t^{p-1}(1 + t)^{-p} \, dt = B(q, p - q) = \frac{\Gamma(q) \Gamma(p - q)}{\Gamma(p)}, \tag{5.6}
\]
where \( B(x, y) := \int_0^\infty t^{p-1}(1 + t)^{-x-y} \, dt \) is the Beta function. This formula can be found, for instance, in [3]. Passing to spherical coordinates and then performing the change of variable \( t = r^{p+1} \), we obtain

\[
\int_{\mathbb{R}^n} U^p \, dx = U_{n-1} \frac{p-1}{p} I_n^{p-1}, \\
\int_{\mathbb{R}^n} |x|^2 U^p \, dx = \omega_{n-1} \frac{p-1}{p} I_n^{p-1} - \frac{2}{p} + 2, \\
\int_{\mathbb{R}^n} |\nabla U|^p \, dx = \omega_{n-1} \frac{p-1}{p} \left( \frac{n-p}{p-1} \right) I_n^{p-1}, \\
\int_{\mathbb{R}^n} |x|^2 |\nabla U|^p \, dx = \omega_{n-1} \frac{p-1}{p} \left( \frac{n-p}{p-1} \right) I_n^{p-1} - \frac{2}{p} + 3.
\]

Then

\[
D(n, p) = \frac{I_n^{(p-1)+1}}{I_n^{(p-1)+2}} = \frac{n(n-p)-2(p-1)}{n+2},
\]

where we used that

\[
I_n^{q+1} = \frac{q}{p-q-1} I_n^q
\]

which follows from (5.6) and the formula \( \Gamma(z+1) = z\Gamma(z) \).

6. Proof of Proposition 5.1

As 0 is a local minimum of \( p(\cdot) \) we can assume that \( p_{2\delta}^+ := \min_{x \in B_{2\delta}} p(x) = p \).

6.1. Proof of (5.1). We first write

\[
\int_{\mathbb{R}^n} f(x) u_\epsilon(x)^q dx = \int_{B_{2\delta} \setminus B_{1/p}} f(x) u_\epsilon(x)^q dx + \int_{B_{1/p}} f(x) u_\epsilon(x)^q dx = I_1(\epsilon) + I_2(\epsilon).
\]

Since \( u_\epsilon(x) \leq 1 \) if \( |x| \geq \epsilon^{1/p} \), we have, letting \( q_{2\delta}^- := \min_{B_{2\delta}} q \) that

\[
I_1(\epsilon) \leq \|f\|_{L^\infty(B_{2\delta})} \int_{B_{2\delta} \setminus B_{1/p}} u_\epsilon(x)^{q_{2\delta}^-} dx
\]

\[
\leq \|f\|_{L^\infty(B_{2\delta})} \epsilon^{-\frac{n-p-q_{2\delta}^-}{n}} \int_{\mathbb{R}^n \setminus B_{-(p-1)/p}} U(x)^{q_{2\delta}^-} dx,
\]

where the integral in the right hand side can be bounded by

\[
C \int_{\epsilon^{-p-1/p}}^{+\infty} (1 + r^{p+1})^{-\frac{n-p-q_{2\delta}^-}{p}} r^{n-1} \, dr \leq C \int_{\epsilon^{-p-1/p}}^{+\infty} r^{-1+\frac{n-p-q_{2\delta}^-}{p}} dr \leq C \epsilon^{-\frac{n-1}{p} + \frac{n-p-q_{2\delta}^-}{p}}.
\]

Hence \( I_1(\epsilon) \leq C \epsilon^{n/p} \) so that

\[
\int_{\mathbb{R}^n} f(x) u_\epsilon(x)^q dx = \int_{B_{1/p}} f(x) u_\epsilon(x)^q dx + O(\epsilon^{n/p})
\]

\[
= \int_{B_{-(p-1)/p}} f(\epsilon x) \epsilon^{n-q(cx)} \frac{n-p}{p} U(x)^{q(cx)} dx + O(\epsilon^{n/p}).
\]
As $\nabla q(0) = 0$, we get
\[
q(\epsilon x) = q(0) + \frac{1}{2} \epsilon^2 (D^2 q(0)x, x) + o(\epsilon^2 |x|^2),
\]
with $q(0) = p(0)^* = p^*$, so
\[
\int_{\mathbb{R}^n} f(x)u_\epsilon(x)^q(x) \, dx = A_0(\epsilon) + A_1(\epsilon)\epsilon^2 \ln \epsilon + \int_{B_\epsilon-1/Cp/n} o(\epsilon^2 \ln \epsilon)|x|^2 U(x)p^* \, dx
\]
\[
+ \epsilon \int_{B_\epsilon-1/Cp/n} U(x)p^* \nabla f(0) \cdot x \, dx + O(\epsilon^{n/p})
\]
\[
= A_0(\epsilon) + A_1(\epsilon)\epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon) + O(\epsilon^{n/p}),
\]
where $A_0(\epsilon)$ and $A_1(\epsilon)$ are the same as $A_0$ and $A_1$ except that we integrate over $B_\epsilon-1/Cp/n$ instead of $\mathbb{R}^n$ and we have used the fact that
\[
\int_{B_\epsilon-1/Cp/n} U(x)p^* \nabla f(0) \cdot x \, dx = 0,
\]
since $U$ is radially symmetric. We have
\[
|A_0(\epsilon) - A_0| \leq C \int_{\mathbb{R}^n \setminus B_\epsilon-1/Cp/n} U(x)p^* \, dx \leq C \int_{\epsilon-1/Cp/n}^{+\infty} (1 + r^{n/p})^{-n} r^{n-1} \, dr
\]
\[
\leq C \int_{\epsilon-1/Cp/n}^{+\infty} r^{-n/p + n-1} \, dr \leq C \epsilon^{n/2p}.
\]
If $p < (n + 2)/2$, we can estimate
\[
|A_1(\epsilon) - A_1| \leq C \int_{\mathbb{R}^n \setminus B_\epsilon-1/Cp/n} |x|^2 U(x)p^* \, dx
\]
\[
\leq C \int_{\epsilon-1/Cp/n}^{+\infty} (1 + r^{n/p})^{-n} r^{n+1} \, dr \leq C \epsilon^{n+2-2p}/p.
\]
We thus have
\[
\int_{\mathbb{R}^n} f(x)u_\epsilon(x)^q(x) \, dx - A_0 - A_1\epsilon^2 \ln \epsilon = O(\epsilon^{n/p}) + o(\epsilon^2 \ln \epsilon),
\]
which reduces to (5.1) if we assume that $p \leq n/2$. \hfill \Box

### 6.2. Proof of (5.3).
As before,
\[
\int_{\mathbb{R}^n} f(x)u_\epsilon^{p(x)} \, dx = \int_{B_{1/p}} f(x)u_\epsilon^{p(x)} \, dx + \int_{B_{2^p} \setminus B_{1/p}} f(x)u_\epsilon^{p(x)} \, dx
\]
where, noticing that $p = p_2^2$, the 2nd integral in the right hand side can be bounded by
\[
\int_{B_{2^p} \setminus B_{1/p}} u_\epsilon^{p} \, dx \leq C \epsilon^p \int_{\epsilon^{1/p-1}}^{1} (1 + r^{n/p})^{p-n} r^{n-1} \, dr \leq C \epsilon^p \epsilon^{n-2p} = C \epsilon^{n/2p},
\]
if $p^2 < n$. Then
\[
\int_{\mathbb{R}^n} f(x)u_\epsilon^{p(x)} \, dx = \int_{B_{1/p}} f(x)u_\epsilon^{p(x)} \, dx + O(\epsilon^{n/2p})
\]
we have with, since

\[
\text{Taking some constant } C > C_p, \text{ we thus write }
\]

\[
\int_{\mathbb{R}^n} f(x) \nabla u_{\epsilon} |^{p(x)} dx = \int_{B_{C_p \frac{n-p}{p-1}}} f(x) \nabla u_{\epsilon} |^{p(x)} dx + \int_{\mathbb{R}^n \setminus B_{C_p \frac{n-p}{p-1}}} f(x) \nabla u_{\epsilon} |^{p(x)} dx + o(\epsilon^p).
\]

6.3. Proof of (5.2). We first write

\[
\int_{\mathbb{R}^n} f(x) \nabla u_{\epsilon} |^{p(x)} dx = \int_{\mathbb{R}^n} f(x) |\nabla U_{\epsilon} + U_{\epsilon} \nabla \eta |^{p(x)} dx = \int_{\mathbb{R}^n} f(x) |\nabla U_{\epsilon} |^{p(x)} dx + R_{\epsilon},
\]

where, using the inequality

\[
||a + b|^q - |a|^q| \leq C(|b|^q + |b||a|^{q-1}),
\]

the constant \(C\) being uniform in \(q\) for \(q\) in a bounded interval of \([0, +\infty)\) we can estimate

\[
|R_{\epsilon}| \leq C \left[ \int_{B_{2\delta} \setminus B_{\delta}} |\nabla \eta| U_{\epsilon}^{p(x)} dx + \int_{B_{2\delta} \setminus B_{\delta}} |\nabla \eta| U_{\epsilon} |\nabla U_{\epsilon} |^{p(x)-1} dx \right] = C[I_1(\epsilon) + I_2(\epsilon)].
\]

Since \(U_{\epsilon} \leq 1\) in \(\mathbb{R}^n \setminus B_{\delta}\) for \(\epsilon\) small, we can bound \(I_1(\epsilon)\) as before by

\[
I_1(\epsilon) \leq C \int_{B_{2\delta} \setminus B_{\delta}} U_{\epsilon}^p dx \leq C\epsilon^p \int_{\mathbb{R}^n \setminus B_{\delta/\epsilon}} U^p dx \leq C\epsilon^{p-n}\frac{\epsilon^{n-p}}{p-1} = C\epsilon^{\frac{n-p}{p-1}},
\]

if \(p^2 < n\). Since \(|\nabla U_{\epsilon}| \leq 1\) in \(\mathbb{R}^n \setminus B_{\delta}\) for \(\epsilon\) small, we also have

\[
I_2(\epsilon) \leq C \int_{\mathbb{R}^n \setminus B_{\delta}} U_{\epsilon}(x)|\nabla U_{\epsilon}|^{p-1} dx \leq C\|U_{\epsilon}\|_{L^p(\mathbb{R}^n \setminus B_{\delta})}\|\nabla U_{\epsilon}\|_{L^p(\mathbb{R}^n \setminus B_{\delta})}^{p-1}
\]

\[
\leq C\epsilon^{\frac{n-p}{p-1}}\|\nabla U_{\epsilon}\|_{L^p(\mathbb{R}^n \setminus B_{\delta})}^{p-1},
\]

with, since \(|U'(r)| \sim r^{-\frac{n-1}{p-1}}\) as \(r \rightarrow +\infty\),

\[
\int_{\mathbb{R}^n \setminus B_{\delta}} |\nabla U_{\epsilon}|^p dx \leq C \int_{\delta/\epsilon}^{+\infty} |U'(r)|^p r^{n-1} dr \leq C\epsilon^{\frac{n-p}{p-1}}.
\]

It follows that \(I_2(\epsilon) = O(\epsilon^{\frac{n-p}{p-1}})\) and then \(R_{\epsilon} = O(\epsilon^{\frac{n-p}{p-1}})\). Independently, since

\[
|\nabla U_{\epsilon}(x)| = \frac{n-p}{p-1}\epsilon^{-n/p} \left(\frac{|x|}{\epsilon}\right)^{\frac{1}{p-1}} \left(1 + \left(\frac{|x|}{\epsilon}\right)^{\frac{1}{p-1}}\right)^{-n/p}
\]

we have

\[
(6.1) \quad |\nabla U_{\epsilon}(x)| < 1 \quad \text{for } |x| > C_p \epsilon^{\frac{n-p}{p-1}}, \quad C_p = \left(\frac{n-p}{p-1}\right)^{\frac{p-1}{p-1}}.
\]

Taking some constant \(C > C_p\), we thus write

\[
\int_{\mathbb{R}^n} f(x) \nabla u_{\epsilon} |^{p(x)} dx = \int_{B_{C_p \frac{n-p}{p-1}}} f(x) \nabla u_{\epsilon} |^{p(x)} dx + \int_{\mathbb{R}^n \setminus B_{C_p \frac{n-p}{p-1}}} f(x) \nabla u_{\epsilon} |^{p(x)} dx + O(\epsilon^{\frac{n-p}{p-1}}).
\]
Since $|\nabla U_\epsilon(x)| < 1$ in $\mathbb{R}^n \setminus B_{C_\epsilon r^{\frac{n-p}{(n-1)p}}}^\frac{n-p}{(n-1)}$, we can bound the second integral on the right hand side by

$$C \int_{\mathbb{R}^n \setminus B_{C_\epsilon r^{\frac{n-p}{(n-1)}}}} |\nabla U_\epsilon|^p \, dx \leq C \int_\epsilon^{+\infty} r^{\frac{n-p}{(n-1)} - 1} r^{n-1} \, dr \leq C \epsilon^{\frac{n(n-p)}{p(n-1)}} = o(\epsilon^{\frac{n-p}{p-1}}).$$

Hence

$$\int_{\mathbb{R}^n} f(x) |\nabla u_\epsilon|^{p(x)} \, dx = \int_{B_{C_\epsilon r^{\frac{n-p}{(n-1)}}}} f(x) |\nabla U_\epsilon|^{p(x)} \, dx + O(\epsilon^{\frac{n-p}{p-1}}) = B_0(\epsilon) + B_1(\epsilon)\epsilon^2 \ln \epsilon + o(\epsilon^2 \ln \epsilon) + O(\epsilon^{\frac{n-p}{p-1}}),$$

where $B_0(\epsilon)$ and $B_1(\epsilon)$ are the same as $B_0, B_1$ but integrating over $B_{r^{\frac{n-p}{(n-1)}}}$ instead of $\mathbb{R}^n$. Again, as in the computation of (5.1), the term involving $\nabla f(0)$ vanishes for symmetry reasons.

Since $|U(r)|^p \sim r^{\frac{p(1-n)}{p-1}}$ as $r \sim +\infty$, we have

$$|B_0 - B_0(\epsilon)| \leq C \int_{\mathbb{R}^n \setminus B_{C_\epsilon r^{\frac{n-p}{(n-1)}}}} |\nabla U|^p \, dx \leq C \int_\epsilon^{+\infty} r^{\frac{n-p}{(n-1)} - 1} \, dr \leq C \epsilon^{\frac{n(n-p)}{p(n-1)}} = o(\epsilon^{\frac{n-p}{p-1}}),$$

$$|B_1 - B_1(\epsilon)| \leq C \int_{\mathbb{R}^n \setminus B_{C_\epsilon r^{\frac{n-p}{(n-1)}}}} |x|^2 |\nabla U|^p \, dx \leq C \epsilon^{\frac{n(n-3p+2)}{3p(n-1)}} \text{ if } p < \frac{n+2}{3}.$$}

Hence, if $p < \frac{n+2}{3}$, we have

$$\int_{\mathbb{R}^n} f(x) |\nabla u_\epsilon|^{p(x)} \, dx - B_0 - B_1 \epsilon^2 \ln \epsilon = o(\epsilon^2 \ln \epsilon).$$
